### Abstract:

In this talk, I will review methods for computing A-optimal sensor placements for Bayesian linear inverse problems governed by PDEs which may contain model uncertainties. A-optimal sensor locations minimize the expected value of the trace of the posterior covariance operator or, equivalently, the trace of the inverse Hessian of a PDE-constrained optimization problem. Choosing from a finite number of given candidate sensor locations is a problem with combinatorial complexity. To find an approximate solution, we relax the problem formulation and use a continuation procedure to find sparse designs. We present numerical results for inference of the initial condition in a subsurface flow problem with uncertainty in the flow fields. I will use material from collaborations with Alen Alexanderian (NC State), Karina Koval (NYU), Noemi Petra (UC Merced), and Omar Ghattas (UT Austin).
